

What your Booking calendar shows today

Checked this morning from public listings only — four units, eight months forward, no access to your systems.

01

Dynamic pricing works — for one week a year

3-bedroom · 9 December	5.2M
3-bedroom · 30 December	9.1M

That is +75%, and it is done well.

The same pattern appears on the other units: +45% and +97% over the New Year period.

Someone on the team knows how to do this.

02

No weekend premium on any unit checked

Sunday 15 November	3.9M
Wednesday 18 November	3.8M

Saturday prices the same as a Tuesday.

The same holds across every month and every unit we opened.

Uluwatu weekends normally carry a material premium.

03

The rate stays flat through the quiet months

February
twenty-eight consecutive days at effectively one price

November
seven days in a row within 2%

The rate does not respond to the day of the week, or to how far ahead the date sits.

The tool that produced +75% in December is switched off.

AND ONE FINDING THAT
IS NOT ABOUT RATE

Across every Airbnb listing we opened, all dates from August 2026 to March 2027 are available. Not one booking in eight months — while the same property carries bookings on Booking.com.

First thirty days — rate work only, no advertising budget

Everything below is done inside the extranet and the channel manager. None of it requires spend.

Weekend premium

Friday and Saturday priced above midweek across the full calendar. Start at 15–20% and test.

Depth-based rate ladder

Further-out dates priced lower, rate rising as the calendar fills. Today the spread between near and far dates is about 15%.

Minimum stay on peak dates

Protects high-value periods instead of leaving one-night gaps in the calendar.

Orphan-night rule

A two-night minimum means a single free night between bookings cannot be sold at all. An exception rule releases those dates instead of losing them.

Early-booking rate

Applied to the months that currently carry no forward demand at all.

Airbnb rebuild and channel parity

Eight months with no bookings on Airbnb is not a demand problem. Sync, pricing, photography and titles reviewed listing by listing against what works on Booking.

WHAT WE CANNOT SEE FROM OUTSIDE

— Realized rate and actual occupancy

— Promotions and discounts applied

— Whether a blank date is booked or simply unsellable

— Channel mix and real commission

— Owner blocks and closed dates

— Cancellations and no-shows

One report closes all of it

Monthly, per unit, last 12 months: nights sold, revenue, platform commission, channel.

From that, realized rate, occupancy, RevPAR and channel mix calculate themselves — with no assumptions from us.
